```

Question 1

a)

As there are many variables available in the dataset, we thought the use of multiple correlation charts to show the correlation throughout the dataset would be the most appropriate. The data has been split into their respected categories as seen in the excel file. The categories are also then compared to the two output variables (108, 109) to show correlation to the outcomes throughout the dataset.

```
corrgram(Residen[,c(1:4, 108, 109)])
```

Residen[,c(1:4, 108, 109)] relates to PROJECT DATES (PERSIAN CALENDAR) START QUARTER has slight negative correlation to all the variables within the correlation chart, and COMPLETION YEAR and COMPLETION QUARTER also have slight negative correlation to each other, as does COMPLETION QUARTER and the output variable V104. COMPLETION QUARTER also only has slight positive correlation to START YEAR and V105 and its negative correlation is stronger than the other negative correlations displayed in this chart. All other variables have strong positive correlations with some lesser positive correlation in relation to V104.

```
corrgram(Residen[,c(5:12, 108, 109)])
```

Residen[,c(5:12, 108, 109)] relates to PROJECT PHYSICAL AND FINANCIAL VARIABLES V1 has negative correlation to all variables except for V7 which shows a weak positive correlation. V2, V3 and V4 all have a strong correlation to each other, and it is also obvious that V4 has a stronger correlation to all other variables, apart from V1 compared to the other variables in the chart. In contrast, V7 has a weak positive correlation to all variables in the chart. V8 shows the strongest correlation to the outcome variables.

```
corrgram(Residen[,c(13:31, 108, 109)])
```

Residen[,c(13:31, 108, 109)] relates to ECONOMIC VARIABLES AND INDICES IN TIME LAG 1 V18 is the variable that has a strong negative correlation to nearly every variable in the chart except for V26 which is a very weak negative and V16 AND V17 which both display strong positive correlation levels. Similar to the last correlation chart where V7 showed more correlation to the negative value and weak positive to all other variables, V26 displays the same characteristics. V12 displays a weaker correlation than the rest of the variables, except V9 but not to the extent of V26. V9 also shows weak positives to all variables apart from the strong positive correlation to V12. Many more variables display high positive correlation to the outcome variables V104 and V105.

```
corrgram(Residen[,c(32:50, 108, 109)])
```

Residen[,c(32:50, 108, 109)] relates to ECONOMIC VARIABLES AND INDICES IN TIME LAG 2 The trend stays mostly the same with V28 displaying the same characteristics as V9 and V31 matching V12 with some minor adjustments in terms of weak to strong positive correlation. V37 is the strong negative correlation in this subset of data. V45 shows weak positives to all variables except for two stronger positive correlations to V35 and V36 and the weak negative to V37. All other variables display a strong positive correlation to the two outcome variables.

```
corrgram(Residen[,c(51:69, 108, 109)])
```

Residen[,c(51:69, 108, 109)] relates to ECONOMIC VARIABLES AND INDICES IN TIME LAG 3 V56 displays the strong negative correlation to all other variables except for the weak positive correlation to V64. V47 displays weak positives to all other variables except for the strong positive correlation to V50. V50 also then shows weak positive correlation to all other variables, although stronger positives in comparison to V47. V54 also shows a weaker positive correlation to all other variables. V64 shows very weak positive correlation to all variables except for V54 and V55 which are strong positives. All other variables display strong positive correlation to the two outcome variables.

```
corrgram(Residen[,c(70:88, 108, 109)])
```

Residen[,89:109] relates to ECONOMIC VARIABLES AND INDICES IN TIME LAG 5 V94 displays a medium negative correlation to all variables except V98, V101, V102 and V104. V98 and V102 show a weak positive correlation to V94 whereas V101 and V104 show a weak negative correlation. V85 and V88 both display a weak positive correlation to all other variables apart from each other which display a strong positive correlation. V102 shows a weak positive correlation to all variables except V92 and V934 which shows as a much stronger positive correlation. All other variables show a high level of positive correlation with the outcome variables.

Overall, there are clear patterns within the dataset, which are present throughout all time lags. There will be fine margins to determine the best features for the model.

b)

```
resdat <- Residen[, -109]

res.mod = lm(resdat$V104 ~ ., data=resdat)
summary(res.mod)

##
## Call:
## lm(formula = resdat$V104 ~ ., data = resdat)
##
## Residuals:
##      Min       1Q   Median       3Q      Max
```

##
## Residual standard error: 148.6 on 296 degrees of freedom
## Multiple R-squared:  0.9879, Adjusted R-squared:  0.9848
## F-statistic: 321.9 on 75 and 296 DF,  p-value: < 2.2e-16
```

We can see that the residuals shown in the summary do not appear to be strongly symmetrical. This means that the model is predicting points that are fairly far away from the actual observed points.

COMPLETION YEAR, COMPLETION QUARTER, V3 and V8 all are highly significant p-values as they are very close to 0. Many of the other variables fall much closer to 1 and are not considered significant to the model. There are also a fair few NA values which means that these variables are more linearly related to the other variables.

The adjusted R-squared value of 0.9848 is very close to 1 which means that it does explain the observed variance in the response variable and that the model fits the actual data fairly well.

The F-statistic shows that the model is performing better than random, which shows how the model can outperform noise as a predictor.

## F-statistic: 1534 on 13 and 283 DF, p-value: < 2.2e-16
```

In terms of time, the stepwise model outperforms the backwards selection model by ~10 seconds. With backwards selection taking 14.00931 secs and stepwise selection taking 4.92289 secs. This time difference really shows how effective each method is with a large dataset as it might be preferable to go with one that performs quicker when facing a much larger dataset. The back.model keeps a lot more of the variables even when they don't have a high level of significance. The residuals are closer to zero but do not show a complete symmetry and still display a high level of difference from the actual variable's vs the predicted. There are 14 variables that show a very high level of significance, 4 variables that show a high level of significance and 8 variables that show a medium level of significance. V8 and V48 show the highest level of significance. The adjusted R-squared variable is 0.9856 which is very close to 1 which is showing that the model is performing very well.

In contrast, the stepwise selection reduces the number of variables significant and all variables on display have a degree of significance. V8 and V72 are the variables with the highest level of significance here. The residuals do have a larger area of error though but still are not symmetrical. The adjusted R-squared is 0.9854 which is 0.0002 lower than the backwards selection method, and the F-statistic is much higher which is relatively larger than 1 given the size of our data. This shows that there is a relationship between the predictor and the response variables.

Holdout MSE's:

```
new.back <- predict(back.model, test)
back.mean <- mean((new.back - test$V104)**2)
back.mean
```

```
## [1] 28122.6
```

```
rmse.back <- sqrt(back.mean)
new.step <- predict(step.model, test)
step.mean <- mean((new.step - test$V104)**2)
rmse.step <- sqrt(step.mean)
step.mean
```

```
## [1] 22287.91
```

The backwards selection model has a much higher holdout MSE in comparison to the stepwise selection holdout MSE. 28122.6 for the backwards selection and 22287.91 for the stepwise selection, this means that the stepwise selection model has performed better than the backwards selection model as the observed and predicted values are closer to one another in the stepwise model.

```
trControl <- trainControl(method="cv",
                          number = 10,
                          search = "random")

caret_model <- train(V104~.,
                    resdat,
                    method="glmStepAIC",
                    direction="backward",
                    trace = F,
                    trControl=trControl)

caret_model

```

Cross-Validation MSE's:

```

as.numeric((caret_model$results[2])**2)

## [1] 31586.92

as.numeric((caret_model2$results[2])**2)

## [1] 28039.12

```

Backwards Selection Cross-Validation MSE: 31586.92 Stepwise Selection Cross-Validation MSE: 28039.12

From the cross validation using caret, we can receive the RMSE for each model. For the backward selection the RMSE is 177.721 and for the stepwise selection the RMSE is 167.4489, squaring these values gives us their respected cross validation MSE. 31586.92 and 28039.12, once again the stepwise model has a much smaller MSE which means that it's model has performed better than the backwards selection model.

Overall, it seems like the stepwise selection model is a better choice for this model as it has a smaller error across all MSE's and is much faster than the backwards selection model. It does have a lower R-squared value but it is only by a small amount so can be easily argued that the pro's outweigh the con's.

d)

```

set.seed(12)

tunegrid <- expand.grid(alpha = 0, lambda = 10**(seq(3,-1,length=100)))
start_time <- Sys.time()
ridge.model <- train(V104~.,
                     train,
                     method="glmnet",
                     tuneGrid = tunegrid,

```

```

                selectionFunction = "best",
                trControl=trControl)
end_time <- Sys.time()
ridge.time <- end_time - start_time

tunegrid1 <- expand.grid(alpha = 1, lambda = 10**(seq(3,-1,length=100)))

start_time <- Sys.time()
lasso.model <- train(V104~.,
                    train,
                    method="glmnet",
                    tuneGrid = tunegrid1,
                    selectionFunction = "best",
                    trControl=trControl)
end_time <- Sys.time()
lasso.time <- end_time - start_time

ridge.time

```

Time difference of 1.082597 secs

```
lasso.time
```

Time difference of 0.7394922 secs

In comparison to the results in part c) these times are much shorter, 1.154985 secs for ridge regression and 0.8203158 secs for lasso time. The code is much cleaner to run and is easier to interpret.

```

num <- coef(ridge.model$finalModel, ridge.model$bestTune$lambda)
num2 <- coef(lasso.model$finalModel, lasso.model$bestTune$lambda)

num

```

```

```
lasso.model$bestTune$lambda
```

```
## [1] 4.977024
```

The dot's present in the outcomes means that the lasso regression “pushed” them out as they didn’t provide

enough new information and therefore are more highly correlated to another variable. This is an interesting contrast as the ridge regression kept all variables. The variables with negative numbers are where V104 will lower as those values get higher, and the high coefficients are where V104 will raise as they raise.

A lambda of 107.2267 was chosen to be the best fit for the ridge regression whereas a lambda of 4.977024 was chosen for the lasso regression.

Holdout MSE's:

```
new.ridge <- predict(ridge.model, test)
ridge.mean <- mean((new.ridge - test$V104)**2)
ridge.mean
```

```
## [1] 53269.94
```

```
rmse.ridge <- sqrt(ridge.mean)

new.lasso <- predict(lasso.model, test)
lasso.mean <- mean((new.lasso - test$V104)**2)
lasso.mean
```

```
## [1] 21675.82
```

```
rmse.lasso <- sqrt(lasso.mean)
```

The holdout MSE's display a very large difference, the Ridge regression has a holdout MSE of 53269.94 whereas the Lasso regression has a holdout MSE of 21675.82. This correlates with the amount of variables that Lasso pushed out as it didn't keep the variables not important to the model which reduced the error significantly in contrast. The Lasso holdout MSE, is around the same values as the holdout MSE's in part c), but is still less than both of them.

Cross-Validation MSE's:

```
ridgeresults <- getTrainPerf(ridge.model)
lassoresults <- getTrainPerf(lasso.model)
```

```
ridgeresults
```

```
##   TrainRMSE TrainRsquared TrainMAE method
## 1   243.0771      0.9669287  167.3756 glmnet
```

```
lassoresults
```

```
##   TrainRMSE TrainRsquared TrainMAE method
## 1   175.0348      0.9845112  103.4267 glmnet
```

```
as.numeric(ridgeresults$TrainRMSE**2)
```

```
## [1] 59086.48
```

```
as.numeric(lassoresults$TrainRMSE**2)
```

```
## [1] 30637.19
```

Once again, the ridge regression cross validation MSE is much higher than the Lasso regression cross validation MSE, with 59086.48 and 30637.19 respectively. Although the Lasso is still within the MSE's in part c) it isn't the lowest MSE of all the models performed.

Overall, the Lasso model has outperformed the Ridge regression, lasso tends to make coefficients to absolute zero in comparison to Ridge which never leads to a coefficient being zero, it only minimises it. This means that Ridge regression is not good for feature reduction. Finally, we would say that Lasso regression has performed the best out of all the models due to its speed, low MSE's and relative ease to understand.

Question 2

a)

```
data = read.csv('parkinsons.csv')

X=model.matrix(UPDRS~.,data=data)[,c(-1,-2)]
y <- data$UPDRS

X <- scale(X)

set.seed(12)
train_ind <- sample(seq_len(nrow(X)), size = 30)
train = X[train_ind,]
test = X[-train_ind,]
linear.mod = lm(y[train_ind] ~ train)
summary(linear.mod)
```

```
##
## Call:
## lm(formula = y[train_ind] ~ train)

```

This model uses too many variables to explain the outcome variable (too complex) and is overfitting the training data. This overfitting means the model is attempting to explain the random variation instead of the true underlying relationship. This model will therefore not perform well on future unseen data and will not perform well when extrapolated

b)

```

grid = 10**(seq(3,-1,length=100))

lasso.mod <- glmnet(X[train_ind,], y[train_ind], alpha=1, lambda=grid, thresh = 1e-10)

set.seed(12)

cv.out <- cv.glmnet(X[train_ind,], y[train_ind], alpha=1, lambda=grid, nfolds=30, thresh = 1e-10)

bestlam <- cv.out$lambda.min
bestlam

```

```
## [1] 1.629751
```

```

lasso.pred <- predict(cv.out, s=bestlam, newx=X[-train_ind,])
opt.test <- mean((lasso.pred - y[-train_ind])^2)
opt.test

```

```
## [1] 10.32915
```

Optimal value of $\lambda = 1.6298$ (4dp) When using the obtained model with the optimal lambda to make predictions on the test data, the resulting test error is 10.3291 (4dp)

c)

```

out = glmnet(X, y, alpha=1, lambda=grid, thresh = 1e-10)
coeff <- predict(out, type="coefficients", s=bestlam)
as.data.frame(coeff[coeff[,1] != 0,])

```

```

##           coeff[coeff[, 1] != 0, ]
## (Intercept)           26.619266
## X97              8.317261

```

The final model is a simple linear regression model, only one feature has been selected.

It has an intercept of 26.62 (2dp) and a coefficient of 8.32 (2dp) for the only explanatory variable, X97.

The other variables have coefficients of 0, which means those coefficients have no part in this model. From this we can conclude that the excluded variables have no statistically significant predictive value for the outcome variable.

d)

```

set.seed(24)
train_ind <- sample(seq_len(nrow(X)), size = 30)
train = X[train_ind,]
test = X[-train_ind,]
grid = 10**(seq(3,-1,length=100))
lasso.mod <- glmnet(X[train_ind,], y[train_ind], alpha=1, lambda=grid, thresh = 1e-10)
cv.out <- cv.glmnet(X[train_ind,], y[train_ind], alpha=1, lambda=grid, nfolds=30, thresh = 1e-10)

```

```
## Warning: Option grouped=FALSE enforced in cv.glmnet, since < 3 observations per
## fold
```

```
bestlam <- cv.out$lambda.min
bestlam
```

```
## [1] 1.963041
```

```
lasso.pred <- predict(cv.out, s=bestlam, newx=X[-train_ind,])
opt.test <- mean((lasso.pred - y[-train_ind])^2)
opt.test
```

```
## [1] 9.032857
```

```
out = glmnet(X, y, alpha=1, lambda=grid, thresh = 1e-10)
coeff <- predict(out, type="coefficients", s=bestlam)
as.data.frame(coeff[coeff[,1] != 0,])
```

```
##           coeff[coeff[, 1] != 0, ]
## (Intercept)          26.619266
## X97              7.979931
```

A different random seed producing a different split of training and test data produces the same simple linear model with the same feature selected, though with a slight variation in value for the coefficients as to be expected from the different test/training split.

It is worth noting that some test/training splits can lead to models with two explanatory variables, the extra one is often X83 and has a very small coefficient value, normally of around 0.3 meaning it has little effect on the final prediction compared to X97.

The small number of observations in this data set explains the high variation in models produced when different random test/training splits are used.

Question 3

a

Overfitting in a regression model occurs when the model is too complex (uses too many variables) and attempts to describe the random variation in the data instead of the true underlying relationships between the variables. An overfit model fits the training data very well but will fit future data poorly, and will also perform poorly when extrapolating the model.

b

Parsimony in regression models means simplicity of the model. A parsimonious model is one with few parameters yet retains high predictive power.

c

The holdout method involves splitting the sample data into training and testing sets, typically in a 2:1 ratio respectively. This means the model can be trained and then tested on separate data to assess performance and reduce overfitting.

The downsides to this method are the splitting of the sample data means less data is available for training so the variance of the models performance estimates is higher.

d

10-fold cross-validation is a typical implementation of K-fold cross-validation where the data is split into 10 random equal sized chunks. 1 chunk is used as the test set while the rest are used as the training sets. This is repeated so that each observation is in a test set once. 10-fold cross-validation solves some of the weakness of the holdout method by in effect making the training data much larger and therefore reducing the variance of the regression estimates of the model. This method is also less dependent on the initial random split of training and testing sets. The disadvantages are increased computational requirements and there is still some variation on each run.

e

A key assumption when using ordinary least squares is the assumption of linearity. If the underlying relationship is non-linear, then this method can produce a model that will perform poorly, especially when predicting extreme outcome values. The best way to identify this problem is visualisation of the data.

Another assumption is that there is a random sampling of variables, this allows for “noise” within the model so that it can perform relatively well on future unseen data.

The conditional mean should be zero, this means that it shouldn’t depend on the independent variables, therefore no relation between X and the error.

The Assumption of Homoscedasticity, if errors are not Homoscedastic then we cannot trust the standard errors within the OLS estimates which means the confidence intervals will not be a good fit.
